

Title: docker-compose use other container as DNS

Post Body:

I have a docker-compose file like:

```
services:  dns-server:      # ...  other:      image: ubuntu      dns: dns-server
```

Is there any way to make the `other` container use `dns-server` as its DNS server without hardcoding the IP of that container? Using the container name doesn't give me an error but it doesn't seem to work.
