Installation

#

PHP Archive (PHAR)

#

We distribute Expose as a PHAR archive that contains everything you need in order to use Expose. Simply download it from [here](#) and make it executable:

```
curl https://github.com/beyondcode/expose/raw/master/builds/expose -L --output expose
```

```
chmod +x expose
```

```
./expose
```

You most likely want to put the `expose.phar` into a directory on your `PATH`, so you can simply call `expose` from any directory. For example:

```
sudo mv expose.phar /usr/local/bin/expose
```

After that, you are ready to go and can [share your first site](#).

Via Composer

#

Expose is a PHP application and you can install the client for your local machine as a global composer dependency:

```
composer global require beyondcode/expose
```

Make sure that your global composer directory is inside of your `PATH` environment variable. Simply add this directory to your `PATH` in your `~/.bash_profile` (or `~/.bashrc`) like this:

```
export PATH=~/.composer/vendor/bin:$PATH
```

As a docker container

#

Expose has a `Dockerfile` in the root of the source that you can build and use without any extra effort.

```
docker build -t expose .
```

Usage:

```
docker run expose <expose command>
```

Examples:

```
docker run expose share http://192.168.2.100 # share a local site
```

```
docker run expose serve my-domain.com # start a server
```

Now you're ready to go and can [share your first site](#).

Extending Expose

#

By default, Expose comes as an executable PHAR file. This allows you to use all Expose features out of the box – without any additional setup required.

If you want to modify Expose and want to add custom request/response modifiers, you need to clone the GitHub repository instead of the global composer dependency.

You can learn more about the customization of Expose in the [extending Expose](#) documentation section.
