Title: docker-compose environment will cover variables in jar, how are docker environment variable and variable in jar mapped? Post Body:

For example, set $environment: EUREKA_PORT=8762$ in docker-compose.yml.

And the variable \${eureka.port=8761} in jar will not effective.

Why environment: EUREKA_PORT=8762 will cover \${eureka.port=8761}?

How are docker environment variable and variable in jar mapped?

Accepted Answer: None Highest Rated Answer:

You are exactly right with your way of thinking - EUREKA_PORT=8762 will set eureka.port through the environment. It's the way it works:

If you use environment variables rather than system properties, most operating systems disallow **period-separated** key names, but you can use **underscores** instead (e.g. SPRING_CONFIG_NAME instead of spring.config.name).

Taken straight from spring documentation.
