Title: Could not locate PropertySource because of java.net.ConnectException: Connection refused

Post Body:

I created a docker image and pushed it to docker hub. Now, I am trying to run it on a remote machine by using `docker-compose` and I get the following error.

```
java.lang.IllegalStateException: Could not locate PropertySource and the fail fast property is set, failing my-test_1  |     at
```

I am guessing it has something to do with ports in one of the config files, but I don't know which one. What is the meaning of this error and where should I look to resolve it? I would appreciate any lead/hint to the problem in the source code/config files. Thank you.

Accepted Answer: None

Highest Rated Answer:

Your Spring Boot app is configured to load properties from a Spring Cloud Config server specified at

http://localhost:8761/config/seodin/prod/master

and it can't see it.

As you are running in Docker either make sure that a config server is running in Docker as well, and that your Spring Boot app is configured to point at that (the URL will not be localhost; it's likely to be the container name of the config server ifyou are running that in Docker, or the URL of an external config server)
